## $\delta$

# NOTES ONLY 

BY KEVIN WHITE FORBES

## FREQUENCY MODIFICATIONS AND POWER CONTROLS FOR THE PHILIPS FM 320

## UHF CB TRANSCEIVER

Transmitting on non C.R.S. (Citizens Radio Service) frequencies is not permitted. Reception of non C.R.S. (UHF C.B.) is permitted. (you are allowed to listen).
This information record is provided for technical and educational purposes only.

## INSTALLING EXTRA CHANNELS

If you are highly superstitious, you probably won't want to continue after I tell you that you have to cut a track that joins two I.C.'s and it runs between pin 13 on both of them. (Humour)

You will need a double pole single throw (dpst) toggle switch.
Thin hookup wire.
A soldering iron and solder.
A little bit of nouse, but not too much.
Let's start our doctoring by removing the top and bottom covers of the radio. You won't have to take off the front panel cover even if you want to personally adjust the high or carrier mute (VR 19) and or the low or noise mute (VR 20) settings. See "Components Layout" page. There are small holes in the circuit board for adustments.

Prepare the toggle switch for installation by soldering on to its three terminals predetermined lengths of end stripped and tinned hookup wire. We shall refer to these wires as A, B, and C. Wire B is the centre wire on the switch or the common.

Let's cut the track that joins pin 13 on IC 3 with pin 13 on IC 5 at the location marked. The idea is to disable the output from IC 5 from the rest of the circuit, it prevents the counter going above 40 . This track is also connected to the front panel display chips.

## INSTALLING EXTRA CHANNELS

Solder wire A to Ground somewhere that is convenient.

The toggle switch could be placed in a hole drilled next to the EXT SPKR socket or remove the socket if it's not used and place the toggle in there.

Wire C must have a resistor on the end of it. Say $1 \mathrm{k} \Omega$ to $3.3 \mathrm{k} \Omega$ should do and the resistor should be soldered to a permanent positive voltage such as the one shown. The resistor may be placed on the switch or on the board, just so long as it's in between the board and the switch.

## INSTALLING EXTRA CHANNELS

Disable the "Transmit Inhibit Circuit" which prohibits transmissions above channel 65 or something by cutting the lead on resistor $\mathbf{R} 287 \mathbf{2 2 K}$.

This will enable transmissions on all 80 channels. 00 to 79

Well that's that bit over, now for a bit of twiddling.
Time to adjust the HF VCO. See the "Components Layout" page for "L9". The ferrite slug in the middle will have to be wound out to the full extent of its travel and perhaps a little bit further as mine had to be.
Keep checking that you have transmit and receive on channels 00 low band and 79 high band.
This VCO is right on its limit providing 2 Mhz of coverage. I had to put a small piece of rolled up paper inside the coil and push the ferrite slug slowly down into it, checking my channels for TX \& RX at the same time, until it was just right, applying some araldite to secure it in place for ever.
You may have to adjust also VR 113 and C 111 single turn trimmer cap UHF VCO.
Make notes of the original positions of these controls BEFORE you start adjusting them.
Rightyo then.
Yo Ho Ho and a bottle of Rum. Let's turn the power up. Oh what fun! Just in case it is not putting out its full allowable 5 watts.

## AUDIO \& POWER ADJUSTMENTS.

When adjusting ferrite slugs in coils, use a plastic tip or a copper tip, copper is a little more forgiving than hard steel tips on brittle ferrite. REMEMBER. Breaking the slug could throw the radio completely off frequency.

VR 11 is the deviation control, turning it fully clockwise produces the narrowest deviation and the best modulation, turning it fully counter clockwise kills audio modulation completely.

Peak the Audio by carefully adjusting $\mathbf{L 4 9}$ while watching the signal strengh meter and receiving a constant strong signal such as a local repeater first. Then $\mathbf{L 4 8}$ and then $\mathbf{L 4 5}$.

If you are having a hard time understanding weak stations through bad audio. Try this. Stick a bit of wire in the antenna socket just long enough to pick up the signals on low mute. With a plastic tip, (inserting a metal tip may change the freq.), VERY carefully adjust C 13 RX Freq. Adj. until the clearest most intelligible signal is heard.

## POWER ADJUSTMENTS:

You need, one SWR/Power meter capale of operating at 477 Mhz connected inline for these adjustments to be made properly. If not, use the radios S/RF Meter.

These should be made with a 50 ohm dummy load flatlined or at the very least an antenna with a SWR lower than 1:1.5 Go to a quiet unused channel. push the transmit button and with a plastic tip, (inserting a metal tip WILL change the freq. and KILL the transmitter.), adjust in this order and very slowly and carefully, C130, C133, C138, C141 and C 142.

You will not get much more than 5 watts out of this radio. My radio had an output power of less than 1 watt when I put on the power meter, not enough to set the calibration on the SWR meter. I watched happily as the needle climbed to 5 watts as I adjusted the controls.

The FM 320 is notorious for not working after getting a bump, it has no chassis to protect it, only its plastic covers. Suspect the solder connections between the front panel and the main circuit board. If this is not the problem try prodding and poking the main board and observe what happens. You may have to re-solder all the joins on the board to find it.

COMPONENTS LAYOUT FM 320. FRONT PANEL \& MAIN BOARD.
